

## NUCLEON TRANSFER PROCESSES IN LOW-ENERGY REACTIONS WITH HELIUM ISOTOPES

Thursday, 14 July 2022 12:30 (30 minutes)

Experimental cross sections for formation of isotopes  $^{44,46}\text{Sc}$  and  $^{45}\text{Ti}$  in reactions  $^{3,4,6}\text{He} + ^{45}\text{Sc}$ ,  $^{196,198}\text{Au}$  in reactions  $^{3,4,6,8}\text{He} + ^{197}\text{Au}$ , and  $^{194}\text{Au}$  in reaction  $^3\text{He} + ^{194}\text{Pt}$  have been analyzed. To calculate nucleon transfer probabilities and cross sections, the time-dependent Schrödinger equation for nucleons of  $^{3,4,6}\text{He}$ ,  $^{45}\text{Sc}$ ,  $^{197}\text{Au}$ , and  $^{194}\text{Pt}$  has been solved numerically with a special choice of the shell model mean field for  $^{3,4,6,8}\text{He}$  nuclei [1] (Fig. 1). Fusion-evaporation channels were taken into account using the code of the NRV web knowledge base [2]. It was shown that the contribution of fusion-evaporation to the experimental data is significant for reactions  $^{3,4,6}\text{He} + ^{45}\text{Sc}$ , whereas in the case of reactions  $^{3,4,6,8}\text{He} + ^{197}\text{Au}$  and  $^3\text{He} + ^{194}\text{Pt}$ , it is negligible. The results of calculation (Fig. 2) are in good agreement with experimental data [3, 4].

Fig. 1. Examples of time evolution of the probability density for the neutron of  $^3\text{He}$  in the collision  $^3\text{He} + ^{197}\text{Au}$  at  $E_{c.m.} = 20$  MeV and impact parameter  $b = 1$  fm. The course of time corresponds to panel locations (a), (b), (c), (d).

Fig. 2. Cross sections for formation of the isotope  $^{198}\text{Au}$  in the reaction  $^3\text{He} + ^{197}\text{Au}$ : experimental data [2] (filled squares) and [3] (empty squares) along with the results of calculations. The arrow indicates the position of the Coulomb barrier.
